Etiological structure of infectious agents in the urinary tract among children

The article presents the results of the research of etiological structure of urinary tract infection among children. Out of the total number of urological and nephrological sick children's research, it is defined that 283 microorganisms selected from the urine were found. 63.2 % of the total number of children in nephrological department is related to only urological diseases. In recent, there has been an open trend to increase a frequency of diseases of the urinary system. Over the past five years, the number of diseases of the genitourinary system in urban children in Kazakhstan has increased to 65 %. The review shows that inflammatory diseases of kidneys and urinary tract take the second place after acute respiratory diseases of upper breathing tract. In this work, it is established that a causative agent of urinary system infection among children is pathogenic, as well as relative-pathogenic microorganisms. As it is shown, the leading etiological agent of uroinfection is *Staphylococcus epidermidis* (13.9 %), *Escherichia coli* (12.2 %), *Enterobacter cloacae* (7.8 %). In some cases, streptococcus are excreted. Also, there were dominant pathogens of nephroinfection among children such as *Escherichia coli* (21.1 %), *Enterococcus faecalis* (9.6 %), *Staphylococcus epidermidis* (20.1 %). Some types of *Candida* fungi in the formation of the urinary tract and kidney infection (mostly *C.albicans* (9.5 %), *C.kruseae* (8.1 %), *C.glabrata* (5.6 %) pathogens) are observed in the study of urine in children. During the general research, it was found that the etiological agents of urinary system among children consist of a huge microbiological spectrum, especially among children living in urban areas.

Keywords: urinary tract infections (UTI), etiology, microflora, accretions, bacteriuria, uropathogen, pyelonephritis, nephrology.

The prevalence of urinary tract infections (UTI) among children remains as an important issue in pediatric nephrology, because this group of diseases takes the first place in the structure of nephropathy compared to other types of glomerulonephritis and kidney disease [1–5].

According to the statistics in recent years of XX century, latent current pyelonephritis (PN) occurs in 2–22 % and asymptomatic forms of bacteriuria have occurred only in 1–3 % of healthy girls, and UTIs are related to the diseases that do not pose a serious threat to children's health [6–8].

And in the recent five years of the XXI century, these indicators have increased from 5 % to 12 % in one city in Kazakhstan, and even the surgical treatment of some recurrent forms of UTIs and structural abnormalities of the urinary tract have caused one of the most complex and dangerous problems in children's lives [9, 10].

In spite of the achievements of theoretical and practical nephrology, the world and Kazakhstan are showing high rates of the prevalence of infectious diseases of the urinary system among children. According to statistics, over the recent five years, the incidence of UTIs among children has increased 1.8 times among children under 14 years, and 2 times among adolescents [11]. The reason for this is the first emerging or developing symptoms in the physiology of adolescents in the past, but, at present, UTIs are also visible in young children and newborns.

Based on the research, it was found that the frequency of nephrological and urological diseases among children and adolescents in the cities of the Irtysh region was due not only to their genetic and medical factors, but also to technogenic pollution of water and air basins [12, 13].

According to this, we are considering a special assessment of the various risk factors that contribute to the development of nephrological and urological diseases of children in the Irtysh region.

The growth rate of statistics shows the highest level for the last three years in the cities on the territory of the Irtysh River (Karaganda city) [14].

While assessing the taxonomic structure of the agents of this pathology in children, it is known that the microorganisms of Enterobacteriaceae (up to 80–90 %) family takes the basic place in the spectrum of bacterial uropathogens. In particular, *E. coli* is a definite leader.

The flora of gram-positive cocci (about 10–20 %) takes the second place, mainly were the bacteria of *Enterococcus* and *Staphylococcus* family. The third group is a group of relatively rare microorganisms,

including non-enzymatic gram-negative bacillus (for example, *Pseudomonas aeruginosa*) and non-spore-forming anaerobes (*Bacteroides* families) and others [15]. Pathogens of *Candida* (mostly *C. albicans*) fungi which cause urinary tract and kidney infections were also found in our research.

The aim of the work: to study the etiological structure of urinary tract infections among children.

Research material and methods

The work is based on the project from January to December which was conducted between 2017–2018 in Karaganda city. A complex of clinical-laboratory test was conducted in the nephrology department of Regional Children's Clinical Hospital (RCCH) for the patients with inflammatory diseases of urinary system, born and brought up only in the city.

First of all, 283 children of nephrological and urological nature were divided into two groups. Quantitative bacteriological method was used to determine the urinary microflora of patients with inflammatory diseases of the urinary system. Material was taken from the patients 1–2 days before the start of antibiotic therapy. The material obtained from the examined individuals was grafted to Endo, Kalin, Saburo and blood agar media. After isolation of the pure culture and gram staining the microorganisms were identified in a microbiological computer analyzer. Types of microorganisms 10^4 and higher than that were taken as etiological factor excreted from the urine. The obtained data were processed by the method of variation statistics. The degree of reliability of the results was estimated by the probability of difference (P) based on the observed numbers of the relative series ($n_1 n_2 \dots$) on the Student's attribute.

The results of research and discussion

283 cultures of microorganisms excreted from the urine of sick children of urological and nephrological nature were studied. In general, 63.2 % of sick children in the nephrology department were registered only with urological diseases.

The urinary microflora of 179 children with urological symptoms in the nephrology department of Karaganda in 2017–2018 is given in Table 1.

Table 1

Etiological structure of the urinary microflora of children with urological diseases in the nephrology department

№	Excreted microorganisms	January – December	
		abs	%, M±m
1	<i>Staphylococcus aureus</i>	4	2.2±1.1
2	<i>Staphylococcus epidermidis</i>	25	13.9±2.5

21	<i>Moraxella catarrhalis</i>	1	0.5±0.5
Total		179	100

The etiological structure of the urinary microflora of sick children in urological discussion was determined by 21 species, as shown in Table 1 below. *Enterococcus faecalis* — 6.8 %, *Enterococcus faecium* — 6.2 %, *Escherichia coli* — 12.5 %, *Staphylococcus epidermidis* — 14 %, *Enterobacter aerogenes* — 7.2 %, *Candida glabrata* — 6.7 %, *Candida kruseae* — 8.3 %, *Candida albicans* — 12.3 %, *Enterobacter cloacae* — 7.8 % are related to dominant species.

The spectrum of microflora isolated from the urine of sick children with urological symptoms is shown in Figure 1.

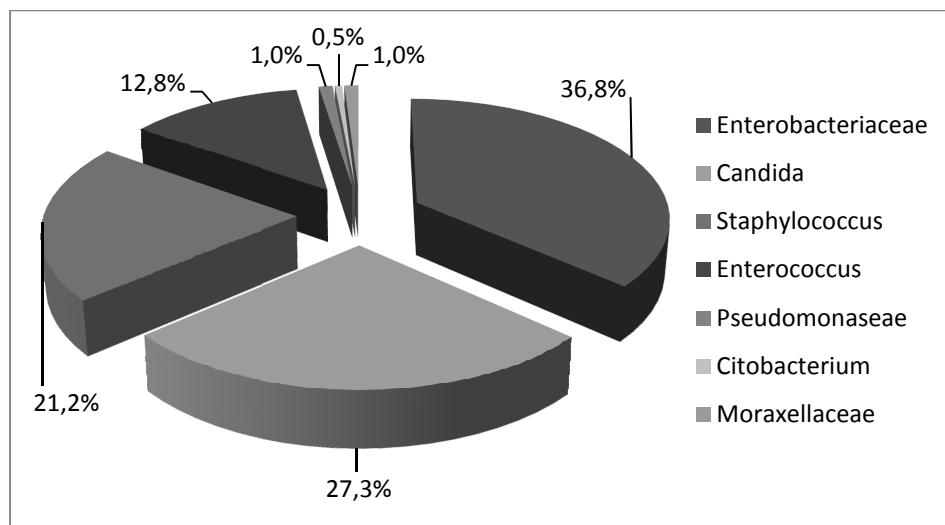

Figure 1. Spectrum of microflora excreted from the urine of sick children with urological symptoms

In the picture below, the first place was taken by the representatives of the family *Enterobacteriaceae* excreted from the urine of children with urological diseases — 36.8 %. It shows this number out of the total quantity of excreted microorganisms, *Enterococcus* relative representatives — 12.8 %, *Staphylococcus* relatives — 21.2 %. Non-fermented gram-negative bacteria taken from the urine of patients with uroinfection were excreted in the amount of 36.8 %, and *Pseudomonas aeruginosa* comprised 1.11 % out of the total number of non fermenting gram negative bacteria (FGNB). 27.3 % is related to *Candida fungi*.

And the urinary microflora of children with nephrological diseases in the children's clinical hospital in Karaganda is given in Table 2. One of the peculiarity of this is the indicators of microbiotic spectrum of children with impaired renal function and those treated for congenital renal insufficiency. The etiological structure of the urinary microflora of children with nephrological diseases in 19 forms is shown in the Table 2.

Table 2

Etiological structure of the urinary microflora of children with nephrological diseases

№	Excreted microorganisms	January – December	
		abs	%, M±m
1	2	3	4
1	<i>Staphylococcus aureus</i>	2	1.9±1.3
2	<i>Staphylococcus epidermidis</i>	21	20.1±3.9
3	<i>Staphylococcus saprophyticus</i>	3	2.8±1.6
4	<i>Enterococcus faecium</i>	1	0.9±0.9
5	<i>Enterococcus faecalis</i>	10	9.6±2.8
6	<i>Escherichia coli</i>	22	21.1±4.0
7	<i>Enterobacter aerogenes</i>	4	3.8±1.9
8	<i>Enterobacter agglomerans</i>	2	1.9±1.3
9	<i>Enterobacter sakazakii</i>	4	3.8±1.9
10	<i>Enterococcus durans</i>	3	2.8±1.6
11	<i>Proteus mirabilis</i>	2	1.9±1.3
12	<i>Klebsiella pneumoniae</i>	1	0.9±0.9

Continuation of Table 2

1	2	3	4
13	<i>Enterobacter cloacae</i>	5	4.8±2.0
14	<i>Hafnia alvei</i>	2	1.9±1.3
15	<i>Pseudomonas aeruginosa</i>	4	3.8±1.9
16	<i>Citrobacter freundii</i>	1	0.9±0.9
17	<i>Candida albicans</i>	5	4.8±2.0
18	<i>Candida kruseae</i>	8	7.6±2.6
19	<i>Candida glabrata</i>	4	3.8±1.9
Total		104	100

In general, 104 cultures were studied. *Enterococcus faecalis* — 9.6 %, *Escherichia coli* — 21.1 %, *Staphylococcus epidermidis* — 20.1 %, *Candida glabrata* — 6.7 %, *Candida kruseae* — 7.7 %, *Candida albicans* — 4.8 %, *Enterobacter cloacae* — 4.8 % are related to dominant species.

Figure 2 shows the spectrum of microflora isolated from the urine of children with nephrological diseases.

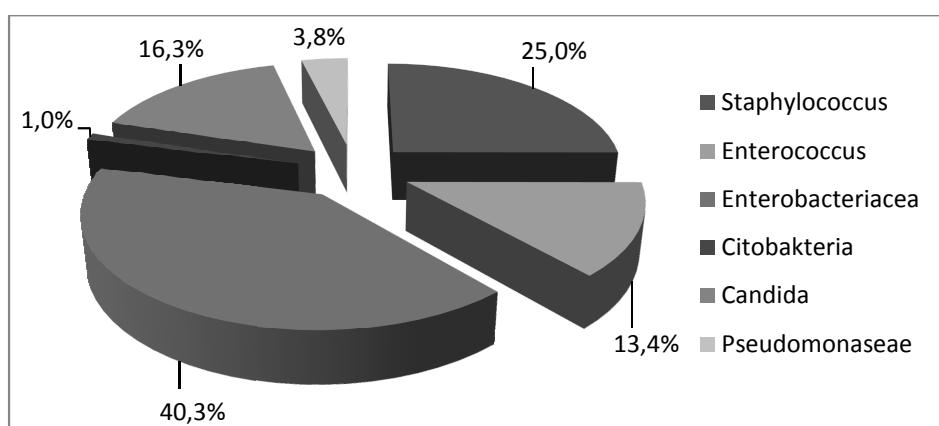

Figure 2. Spectrum of microflora isolated from the urine of children with nephrological diseases

As it is shown in Figure 2, 40.3 % of *Enterobacteriaceae* family takes the first place to be excreted from the urine of children with nephrological symptoms. *Enterococcus* takes the second place, 13.4 % of the total number of excreted microorganisms is related to its fraction. 26 cultures were included in *Staphylococcus* relative, it comprised 25.1 %. Fungi are separated in the amount of 16.3 %.

Conclusion

Thus, the research revealed that out of a total of 283 cultures are divided into two sections, urological and nephrological, the leading of urinary tract infections can be pathogenic, as well as relative-pathogenic microorganisms to etiological agents. In our research, the etiological structure of the pathogens of urinary tract infections of children was the leading agent *Staphylococcus epidermidis* (16.2 %), *Escherichia coli* (15.5 %), *Enterococcus faecalis* (7.7 %), *Enterobacter cloacae* (4.9 %), *Enterobacter aerogenes* (4.5 %).

According to world statistics, the first row of urinary tract infections *Escherichia coli* accounts for 90 %, *Enterococcus* 5–7 %, *Klebsiella* 4–6 %. And our research shows that the class of bacilli is dominated by the bacterium *Staphylococcus epidermidis*. It is a conditionally pathogenic bacterium that causes purulent infection of the skin mucosa of the urinary system.

Балалар арасында зэр шығару жолдарындағы инфекциялық қоздырғыштардың этиологиялық құрылымы

Макалада балалар арасында зэр шығару жолдары инфекциясының этиологиялық құрылымының зерттеу нәтижелері көрсетілген. Жалпы зерттелінген урологиялық және нефрологиялық наукас балалар несептерінен бөлініп алынған 283 микроорганизм күннелерінде жалпы нефрология бөліміндегі наукас балалардың 63,2 %-ы тек урологиялық ауруға шалдықкандар катарында екені белгілі болды. Соңғы жылдардың несеп шығару жүйесі мүшелерінің ауруға шалдығу жиілігінің өсуіне ашық тенденция байқалған. Соңғы бес жыл аралығында Қазақстанда несеп-жыныстық жүйесінің ауру саны қалада тұратын балаларда 65 % дейін өсіксін. Бүйрек және несеп жолдарының қабыну аурулары беткі тыныс алу жолдарының өткір респираторлы ауруларынан кейін екінші орынды алатындығы бойынша шолу жасалынған. Бұл зерттеуде балалар арасында несеп шығару жүйесі инфекциясының қоздырғышы патогенді, сонымен бірге, шартты-патогенді микроорганизмдердің бола алатыны анықталынған. Көрсетілгенде, уроинфекцияның жетекші этиологиялық агенті *Staphylococcus epidermidis* (13,9 %), *Escherichia coli* (12,2 %), *Enterobacter cloacae* (7,8 %) болып табылады. Кей жағдайда ғана стрептококкалар бөлініп алынған. Сонымен кatar балалар арасында нефроинфекцияның доминанттық қоздырғышы *Escherichia coli* (21,1 %), *Enterococcus faecalis* (9,6 %), *Staphylococcus epidermidis* (20,1 %) болып шықты. Зэр шығару жолдары мен бүйрек инфекциясының қалыптасуында *Candida* санырауқұлактарының кейбір түрлері (көбінесе *C. albicans* (9,5 %), *C. kruseae* (8,1 %), *C. glabrata* (5,6 %) қоздырғыштары) балалар несебін зерттеулер кезінде айтартылғатай кездесіп отырғаны байқалған. Жалпы зерттеу барысы кезінде балалар арасындағы зэр шығару жүйесінің этиологиялық қоздырғыштарының орасан үлкен микробиоталық спектрден тұратыны, әсіресе қалалық аумакта тұратын балалар арасында жиі кездесетін түрлері анықталған.

Кітт сөздер: зэр шығару жолдары инфекциясы (ЗШЖИ), этиология, микрофлора, өсінділер, бактериурия, уропатоген, пиелонефрит, нефрология.

Этиологическая структура инфекционных возбудителей мочевыводящих путей среди детей

В статье представлены результаты исследования этиологической структуры инфекций мочевыводящих путей у детей. Из 283 микроорганизмов, выделенных из мочи детей с урологическими и нефрологическими заболеваниями, 63,2 % детей с общей нефрологией были диагностированы только с урологическими заболеваниями. В последние годы наметилась четкая тенденция к увеличению заболеваемости мочевыделительной системы. За последние пять лет в Казахстане количество заболеваний мочеполовой системы городских детей возросло до 65 %. Воспалительные заболевания почек и мочевыводящих путей считаются вторыми после острых респираторных заболеваний верхних дыхательных путей. В этом исследовании было установлено, что возбудителем инфекций мочевыводящих путей у детей могут быть как патогенные, так и условно-патогенные микроорганизмы. Показано, что основными этиологическими агентами уроинфекции являются *Staphylococcus epidermidis* (13,9 %), *Escherichia coli* (12,2 %), *Enterobacter cloace* (7,8 %). В некоторых случаях стрептококки были изолированы. Кроме того, доминирующими возбудителями нефроинфекции среди детей выступили *Escherichia coli* (21,1 %), *Enterococcus faecalis* (9,6 %), *Staphylococcus epidermidis* (20,1 %). Обнаружено, что возбудители *C. albicans* (9,5 %), *C. kruseae* (8,1 %), *C. glabrata* (5,6 %) значимы в моче детей. В целом, исследования показали, что мочевыделительная система у детей состоит из огромного количества этиологических патогенов, особенно среди детей, живущих в городских районах.

Ключевые слова: инфекции мочевыводящих путей, этиология, микрофлора, штаммы, бактериурия, уропатогены, пиелонефрит, нефрология.
